Transportation Electrification Cost-benefit Analysis

EV Roadmap 9 July 20, 2016

Eric Cutter Director, Distributed Energy Resources B MDV/HDV sectors are very diverse California Utilities' Service Territory Costs & Benefits

Truck Stop

Buses Trucks **Electrification** \$50,000 \$700,000 \$1,600,000 \$70,377 \$1,211,653 \$13,474 🗖 Net Benefit \$45,000 \$1,400,000 RPS Cost \$600,000 Costs \$40,000 T&D Cost Present Value \$Per Vehicle \$1,200,000 Carbon Cost \$500,000 \$35,000 Capacity Cost \$1,000,000 \$30,000 Energy Cost \$400,000 \$25,000 Utility Charger Cost \$800,000 \$300,000 Customer Charger Cost \$20,000 \$600,000 Incremental Vehicle Cost \$15,000 \$200,000 \$400,000 Carbon Benefits \$10,000 \$100,000 Benefits \$200,000 \$5,000 Gasoline Savings **\$0 \$0** \$0 **Benefits Benefits** Costs Benef Costs Vehicle cost and **High Charging Avoid inefficient** availability varies widely **Demand (kW)** idling

Energy+Environmental Economics

Medium Duty

- + Incremental load per customer is higher for fleet vehicles, increasing the efficiency of administrative spending
- + Fleet vehicles charge reliably and are paired specifically with charging infrastructure, reducing the risk of stranded infrastructure assets
- Many fleet vehicles (buses, taxis, trucks) are highly visible to public, providing educational benefits that can further adoption
- + Encouraging adoption for EVs other than LDVs reinforces that EVs are not only for the wealthy
- + Often occur in disadvantaged communities, providing social equity opportunities
- Can suffer from market failure of split incentives between site hosts and vehicle operators, creating strong case for utility investment

 Relative to 'traditional' class average loads, PEV loads may differ for:

+ Cost Allocation

• Capacity costs attributable to PEV load may be lower

+ Coincidence with Peak Load

- PEV peaks can be shorter duration (e.g.15 min. vs. 4 hours), with lower cost impacts
- PEV peak loads may have lower probability of coincidence with other customer loads

+ Billing Determinant

 Billing determinant (e.g. non-coincident peak demand) may cause PEVs to pay more than their share

Cost-benefit analysis is driven by goals

+ Utility Cost-effectiveness Framework

- reduce cost and emissions required to meet <u>forecasted</u> <u>loads</u> with distributed <u>energy</u> resources
- Compare <u>cost of delivered electricity</u> to <u>conventional</u> resource plan (\$/kWh, \$/kW-Yr.)
- Evaluate marginal changes in energy sector

+ GHG Pathways Framework

- Minimize costs to achieve <u>forecasted GHG</u> <u>reductions</u> across <u>energy</u>, <u>transportation</u> and <u>industrial</u> sectors
- Compare <u>cost of carbon reduction</u> in <u>transformational</u> resource plans (*Hint: not just comparing \$/ton*)
- Evaluate <u>systemic changes</u> across multiple sectors

But energy efficiency approach is only partially applicable

Useful Tools from EE

Established methods for calculating 'avoided cost' (benefits)

Established cost-benefit framework

Using 'total' and 'societal' benefits to justify utility ratepayer funding

Emphasis on transparency and stakeholder process

Utility role in bridging market gaps and barriers

Key Differences for TE

Requires coordination across utility and transportation sectors

Nascent market with many unknowns outside energy sector

Hard to 'attribute' increase in adoption to specific actions or actors

Risk of stranded assets if EV adoption is low

Transportation electrification poses different threshold questions for regulators (and stakeholders)
